What's happened: **the road to accident**

- User power on his laptop and complete the login process with his username and password;
- a Huawei USB stick (UMTS) has been plugged in;
- Internet connection has been established via USB UMTS modem;
- user browses on xhamster[.]com domain and search for a keyword («flashing»);
- after 14 pages the malicious ADS frame has been rendered by Firefox browser, starting the redirection to malicious content;

Digital Forensic Investigation bookmark #1

User browses 15 pages of search results for the keyword «flashing» on «it[.]xhamster[.]com» via Mozilla Firefox, then he displays the malicious banner within the results page

Digital Forensic Investigation bookmark #3

Chrome will block iframe redirects

The first of these three features — and the most important — will land in Chrome 64, scheduled for an official release in late January 2018.

Starting with v64, Chrome will block URL redirection attempts triggered by code loaded inside iframes embedded in a page.

Most website owners don't use iframes when creating their sites and iframes usually end up on a page loaded via ads.

Malicious ads — also known as malvertising — will use JavaScript code loaded inside these iframes to redirect users to malicious sites.

By blocking iframes from redirecting users to new sites, Google will be putting a huge dent in malvertising campaigns starting next year.

Source: <https://www.bleepingcomputer.com/news/security/google-adds-new-features-in-chrome-to-fight-malvertising/>

Digital Forensic Investigation bookmark #4

Malvertising campaigns can exploit the profiling capabilities of ADS networks, in order to target only selected users (country, industry sector, interests, user behaviour, etc...). In this case the malicious ADS uses profiling keywords «voyeur», «public» and «nudity» correlated to the typed keyword «flashing»

Incident Response Case Management #1

Case details

Case metadata as TLP and Tags

Easily correlate events and incidents

The screenshot shows the TheHive interface for Case #31 - Kovtar malvertising. The top navigation bar includes 'TheHive', 'New Case', 'My tasks 0', 'Waiting tasks 55', 'Alerts 1523', and 'Dashboards'. The case header shows 'Case #31 - Kovtar malvertising', 'Created by Andrea Minigozzi', 'Tue, Oct 10th, 2017 10:50 +02:00', and '1 Related case'. Below the header are tabs for 'Details', 'Tasks 0', 'Observables 12', and 'Related Cases 0'. The 'Details' tab is active, showing a 'Summary' section with the following metadata: Severity (M), TLP (TLP:AMBER), Title (Kovtar malvertising), Assignee (Andrea Minigozzi), Date (Tue, Oct 10th, 2017 10:50 +02:00), and Tags (CNAIPIC, kovtar, malvertising). The 'Description' section contains a detailed paragraph about a large-scale malvertising campaign by KovCoreG (also known as MaxTDS), which targeted users of Chrome, Firefox, and Edge browsers through FlashPlayer, redirecting them to a malicious site on Pornhub. The campaign used JavaScript code to download a PowerShell script and execute a payload. The text notes that the attack was highly sophisticated and targeted millions of users in the US, Canada, UK, and Australia. On the right side, there are sections for 'Additional information' (no info specified), 'Metrics' (no metrics set), and 'Related cases' (Newest: Case #20 - test case, Created on 2017-09-06, Shares 9 observables, Tagged as test). A 'See all (1 related case)' link is also present.

9. StopForumSpam: contributed by Marc-André Doll from STARC (by EXAPROBE)
10. ThreatCrowd: contributed by Rémi Allain from Cyberprotect
11. Unshortenlink: contributed by Rémi Pointel from CERT-BDF

The screenshot shows the GitHub profile for LDO-CERT. The profile includes a search bar, repository filters (Type: All, Language: All), and a list of repositories. The repositories listed are:

- MISP**: Forked from MISP/MISP. MISP - Malware Information Sharing Platform & Threat Sharing. PHP, 476 stars, AGPL-3.0 license, updated 7 days ago.
- Cortex-Analyzers**: Forked from TheHive-Project/Cortex-Analyzers. Cortex Analyzers Repository. Python, 65 stars, AGPL-3.0 license, updated 14 days ago.
- cuckoo**: Forked from cuckoosandbox/cuckoo. Cuckoo Sandbox is an automated dynamic malware analysis system. JavaScript, 1,171 stars, updated on 31 Jan.
- PyMISP**: Forked from MISP/PyMISP. Python library using the MISP Rest API. Python, 132 stars, updated on 23 Jan.
- misp-objects**: Forked from MISP/misp-objects. Definition, description and relationship types of MISP objects. Shell, 28 stars, updated on 23 Jan.

Tools used during the investigation:

EnCase Forensic has been used for Digital Forensic on the acquired Hard Disk image.

MISP has been used to share IoC

The Hive has been used to manage the case, the actions and analyze indicators

Mandiant Redline has been used to analyze malicious artifacts

SANS SIFT Workstation (FOR.508) has been used primarily to analyze RAM dump via volatility and then to process several other Windows artifacts.

Attack attribution and Cyber Threat Intelligence enrichment

KOVTER GROUP MALVERTISING CAMPAIGN EXPOSES MILLIONS TO POTENTIAL MALWARE

OCTOBER 06, 2017 Kafeine and Proofpoint Staff

Overview

Proofpoint researchers recently detected a large-scale malvertising attack by the so-called KovCoreG group, best known for distributing Kovter ad fraud malware and sitting atop the affiliate model that distributes Kovter more widely. This attack chain exposed millions of potential victims in the US, Canada, the UK, and Australia, leveraging slight variations on a fake browser update scheme that worked on all three major Windows web browsers. The attack has been active for more than a year and is ongoing elsewhere, but this particular infection pathway was shut down when the site operator and ad network were notified of the activity.

Based on OSINT information available in MISP and The Hive platform, we can easily and quickly attribute the incident to **Kovter Group** and its malvertising campaign. The original Proofpoint® report has been used to confirm step-by-step our investigation and findings.

The victim's computers was not infected by the malware due a lucky timing: when the user browsed the infected site, a redirection chain started but the exploit kit wasn't delivered due the change of the domain name, few hours before the signature alert.

LESSON LEARNED #1

- **Usable** and **applicable** security policy;
- **Awareness** about cyber risks, through **periodically and dedicated actions** vs users targetted by cybersecurity incident, improving training and communication;
- Apply **disciplinary measures** for policy violation;
- **Limit** the use of external connection, considering the exception or special needs driven by the business, improving security controls also **evaluating the «security posture»** of the user before allowing the exception.

LESSON LEARNED #2

Create a dedicated intranet portal accessible by all employees to inform about security and cyber security threats.
